- Buffer Overflow Vulnerability

Memory Layout of a Program (x86)

Code

The program code: fixed size and read only

Static data

Statically allocated data, e.g., variables, constants

Stack

- Parameters and local variables of methods as they are invoked.
- Each invocation of a method creates one frame which is pushed onto the stack
- Grows to lower addresses

Heap

- Dynamically allocated data, e.g., class instances, data array
- Grows towards higher addresses

Memory layout High Addr Code Static data Stack

Low Addr

Heap

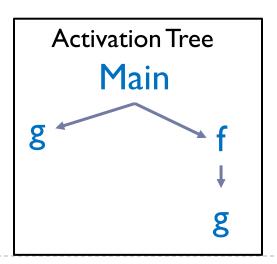

Stack

Store local variables (including method parameters) and intermediate computation results

A stack is subdivided into multiple frames:

- A method is invoked: a new frame is pushed onto the stack to store local variables and intermediate results for this method;
- A method exits: its frame is popped off, exposing the frame of its caller beneath it

```
Main( ) {
    g( );
    f( );
}
f( ) {
    return g( );
}
g( ) {
    return 1;
}
```

Main's frame g's frame g's frame

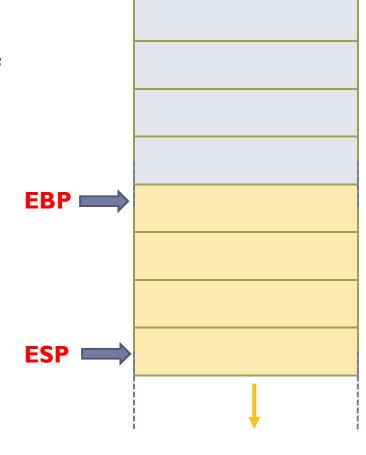

Inside a Frame for One Function

Two pointers:

- EBP: base pointer. Fixed at the frame base
- ESP: stack pointer. Current pointer in frame (current lowest value on the stack)

A frame consists of the following parts:

- Function parameters
- Return address of the caller function
 - When the function is finished, execution continues at this return address
- Base pointer of the caller function
- Local variables
- Intermediate operands

Initially: EBP and ESP point to the top and bottom of the bar stack frame.

```
EBP 

              bar stack frame
ESP I
```

```
void bar( ) {
  foo(1, 2);
}
int foo(int x, int y){
  int z = x + y;
  return z;
}
```

Step I: Push function parameters to the stack.

- Function parameters are stored in reverse order.
- ESP is updated to denote the lowest stack location due to the push operation.

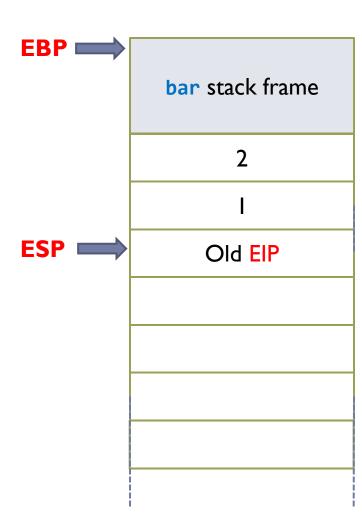

```
void bar( ) {
  foo(1, 2);
}
int foo(int x, int y){
  int z = x + y;
  return z;
}
```

Step 2: Push the current instruction pointer (EIP) to the stack.

- This is the return address in function bar after we finish function foo.
- ESP is updated to denote the lowest stack location due to the push operation.

```
void bar( ) {
  foo(1, 2);
}
int foo(int x, int y){
  int z = x + y;
  return z;
}
```

Step 3: Push the EBP of function bar to the stack.

- This can help restore the top of function bar stack frame when we finish function foo.
- ESP is updated to denote the lowest stack location due to the push operation.

```
void bar() {
  foo(1, 2);
}
int foo(int x, int y){
  int z = x + y;
  return z;
}
```
